

# Assignment 4, Design Specification

SFWRENG 2AA4

April 16, 2021

This Module Interface Specification (MIS) document contains the modules necessary to implement the model and the view of the game *2048*. At the start of the game, the player will see a 4x4 board containing 16 cells. Two random cells will contain either two 2 tiles, or one 2 tile and one 4 tile. The player can then move the tiles either up, down, left, or right, and the tiles slide over in that direction as far as they can go, unless they are blocked by the edge of the board, or another tile. If the tiles that slide together are the same, then they combine to create a single tile whose value is two times its original value. Therefore, all cells are either empty, or contain a tile whose value is  $2^n$ , where  $n$  is a natural number not including 0. For this implementation, the empty cells will be represented by a 0 tile. A visualization of the game board and an example of a move `right` is shown below:

# 1 Overview of the design

This design applies Model View Controller (MVC) design pattern, where *BoardT* is the model module and *View* is the view module. The module *BoardT* stores the state of the game board and the status of the game, while the view module *View* displays the current state of the game board and the overall game using text-based (ASCII) graphics. There is no controller module in this implementation.

### **Likely Changes my design considers:**

- Data structure used for storing the game board
- 
- 
- Change in game ending conditions to adjust the difficulty of the game.

# Board ADT Module

## Template Module

BoardT

## Uses

None

## Syntax

### Exported Types

None

### Exported Constant

size = 4    // Size of the board 4 x 4

### Exported Access Programs

Routine name	In	Out	Exceptions
BoardT		BoardT	
getBoard		seq of (seq of $\mathbb{N}$ )	
getScore		$\mathbb{N}$	
getHighScore		$\mathbb{N}$	
emptyCells		set of (seq of $\mathbb{N}$ )	
isGameWon		$\mathbb{B}$	
isGameLost		$\mathbb{B}$	
setBoard	seq of (seq of $\mathbb{N}$ )		IllegalArgumentException
resetBoard			
isValidMoveRight		$\mathbb{B}$	
isValidMoveLeft		$\mathbb{B}$	
isValidMoveUp		$\mathbb{B}$	
isValidMoveDown		$\mathbb{B}$	
moveRight			
moveLeft			
moveUp			
moveDown			

## Semantics

### State Variables

board: sequence [size, size] of  $\mathbb{N}$

score:  $\mathbb{N}$

highscore:  $\mathbb{N}$

empty: set of (sequence of  $\mathbb{N}$ )

win:  $\mathbb{B}$

lose:  $\mathbb{B}$

### State Invariant

$$0 \leq |empty| \leq 14$$

$$0 \leq score \leq highscore$$

### Assumptions

- The constructor BoardT is called for each object instance before any other access routine is called for that object.
- Assume there is a random function that generates a random value between 0 and 1.
- *highscore* is a static variable.
- The seq of (seq of  $\mathbb{N}$ ) provided as input for the *setBoard* method will consist of correct numbers. This means that the numbers will be either 0 to represent an empty cell, or  $2^n$ , where  $n \neq 0$ .
- The set of (sequence of  $\mathbb{N}$ ) used to represent the state variable *empty* will contain the coordinates for the empty cells of the game board. The sequence of  $\mathbb{N}$  will only contain two numbers to represent the row and column of an empty cell. For example, *empty* will be a set of  $[row, column]$ .

### Access Routine Semantics

BoardT():

- transition:  
$$board := \langle \begin{matrix} \langle 0, 0, 0, 0 \rangle \\ \langle 0, 0, 0, 0 \rangle \\ \langle 0, 0, 0, 0 \rangle \\ \langle 0, 0, 0, 0 \rangle \end{matrix} \rangle$$

where two random empty cells are replaced with two 2 tiles or one 2 tile and one 4 tile.

score, win, lose = 0, False, False

$empty := \forall i, j : [0 \dots size - 1] | (board[i][j] = 0 \Rightarrow empty \cup \{\langle i, j \rangle\} \mid True \Rightarrow empty - \{\langle i, j \rangle\})$

- output:  $out := self$
- exception: None

getBoard():

- output:  $out := board$
- exception: None

getScore():

- output:  $out := score$
- exception: None

getHighScore():

- output:  $out := highscore$
- exception: None

emptyCells():

- output:  $out := empty$
- exception: None

isGameWon():

- output:  $out := win$
- exception: None

isGameLost():

- output:  $out := lose$
- exception: None

setBoard( $b$ ):

- transition:  $\text{board} := b$
- output: None
- exception:  $\text{exc} := ((\neg (|b| = 4) \Rightarrow \text{IllegalArgumentException}) \mid (\forall (i : [0 \dots \text{size} - 1] \mid \neg (|b[i]| = 4) \Rightarrow \text{IllegalArgumentException})))$

resetBoard():

- transition:
 
$$\text{board} := \langle \begin{matrix} \langle 0, 0, 0, 0 \rangle \\ \langle 0, 0, 0, 0 \rangle \\ \langle 0, 0, 0, 0 \rangle \\ \langle 0, 0, 0, 0 \rangle \end{matrix} \rangle$$

where two random empty cells are replaced with two 2 tiles or one 2 tile and one 4 tile.

score, win, lose = 0, False, False

$\text{empty} := \forall i, j : [0 \dots \text{size} - 1] \mid (\text{board}[i][j] = 0 \Rightarrow \text{empty} \cup \{\langle i, j \rangle\} \mid \text{True} \Rightarrow \text{empty} - \{\langle i, j \rangle\})$
- output: None
- exception: None

isValidMoveRight():

- output:  $\forall i : [0 \dots \text{size} - 1] (\forall j : [0 \dots \text{size} - 2] \mid (\text{board}[i][j] \neq 0 \wedge \text{board}[i][j + 1] = 0 \Rightarrow \text{True} \mid \text{board}[i][j] = \text{board}[i][j + 1] \wedge \text{board}[i][j], \text{board}[i][j + 1] \neq 0 \Rightarrow \text{True} \mid \text{True} \Rightarrow \text{False}))$
- exception: None

isValidMoveLeft():

- output:  $\forall i : [0 \dots \text{size} - 1] (\forall j : [\text{size} - 1 \dots 1] \mid (\text{board}[i][j] \neq 0 \wedge \text{board}[i][j - 1] = 0 \Rightarrow \text{True} \mid \text{board}[i][j] = \text{board}[i][j - 1] \wedge \text{board}[i][j], \text{board}[i][j - 1] \neq 0 \Rightarrow \text{True} \mid \text{True} \Rightarrow \text{False}))$
- exception: None

isValidMoveUp():

- output:  $\forall i : [size - 1 \dots 1] (\forall j : [0 \dots size - 1] \mid (board[i][j] \neq 0 \wedge board[i - 1][j] = 0 \Rightarrow True \mid board[i][j] = board[i - 1][j] \wedge board[i][j], board[i - 1][j] \neq 0 \Rightarrow True \mid True \Rightarrow False))$
- exception: None

isValidMoveDown():

- output:  $\forall i : [0 \dots size - 2] (\forall j : [0 \dots size - 1] \mid (board[i][j] \neq 0 \wedge board[i + 1][j] = 0 \Rightarrow True \mid board[i][j] = board[i + 1][j] \wedge board[i][j], board[i + 1][j] \neq 0 \Rightarrow True \mid True \Rightarrow False))$
- exception: None

moveRight():

- transition:

## Access Routine Semantics

`printWelcomeMessage()`:

- transition: `terminal :=` Displays a welcome message when the player begins the game for the first time.

`printBoard()`:

- transition: `terminal :=` Displays the game board. The cells can be accessed by using the *getBoard* method from *BoardT*. The board is displayed as a 4x4 matrix, so each row of cells is on a separate line. The `board[x][y]` is displayed so that x increases as you go right across the screen, and y increases as you go down the screen.

`printMovePrompt()`:

- transition: `terminal :=` Displays a prompt asking the player to select which direction they want to move the tiles.

`printScore(b)`:

- transition: `terminal :=` Displays the current score of the game, which can be accessed by using the *getScore* method from *BoardT*.

`printHighScore(b)`:

- transition: `terminal :=` Displays the best/highest score of the game, which can be accessed by using the *getHighScore* method from *BoardT*.

`printLosingMessage()`:

- transition: `terminal :=` Displays a message telling the player they lost, then displays a prompt asking the player if they would like to try again or exit the game.

`printWinningMessage()`:

- transition: `terminal :=` Displays a message telling the player they won, then displays a prompt asking the player if they would like to continue the current game, start a new game, or exit the game.

`printFarewellMessage()`:

- transition: `terminal :=` Displays a farewell message after the player decides to exit the game.

## Critique of Design

- The BoardT module is an abstract data type instead of an abstract object. This is so multiple instances can be created at a time, and therefore, multiple games can be played. Player A does not have to reset their game if Player B wants to start their own game. Also, this makes it easier to implement the *resetBoard()* method for if the player would like to reset the game.
- The View module is implemented as a library of methods. This is because the View module only contains methods that print out different messages along with the current state of the board. That means you don't need to create an instance of a View to use the methods, you can just call them when needed.
- The *resetBoard()* method from the BoardT module is not essential, since instead of resetting the board/game, you can also just create a new instance of the board.
- The *emptyCells()* method from the BoardT module is also not essential. You can figure out which cells are empty by looking at the board, which you can see by using the *getBoard()* method.
- The BoardT module is not minimal. This is because *resetBoard()*, *moveRight()*, *moveLeft()*, *moveUp()*, and *moveDown()* all make changes to multiple state variables at once. For example, *moveRight()* changes the state of the board, the score, the empty cells, and possibly even win, lose, and the highscore.
- I could have applied the strategy design pattern and made the implementation more general if I created interfaces for the *isValidMove* and *move* methods. There was a lot of repetition implementing them all (*isValidMoveRight*, *isValidMoveLeft*, *moveRight*, *moveLeft*, etc.), ???
- The *setBoard* method is mostly for the programmer and can be used for testing purposes. This way you know what the board looks like, and it is not randomly generated. A randomly generated board makes it difficult to use automated testing.
- test cases?
- Applying MVC (or MV in this case) improves the maintainability of the design. It also applies separation of concerns since the model module and view module contain independent stuff. The model module handles the status etc and the view module displays the current state of the game.
- the MVC design pattern (?) promotes high cohesion

- the MVC design pattern also promotes low coupling since the model and view modules are almost entirely independent of each other. this way changing one module will not greatly affect the other module.

Q1: Draw a UML diagram for the modules in A3.

Q2: Draw a control flow graph for the convex hull algorithm.

The diagrams for these questions are below:
